

Let G be a group and suppose X is a nonempty set of elements of G . The **subgroup generated by X** is the smallest subgroup of G that contains X . For example, the subgroup of \mathbb{Z}_{12} generated by the set $\{4, 6\}$ is $\{0, 2, 4, 6, 8, 10\}$ (explained below). For a single element $g \in G$, we often denote the subgroup generated by the set $\{g\}$ by $\langle g \rangle$ instead of $\langle \{g\} \rangle$. For finite sets, like $\{x, y\}$, we often write, $\langle x, y \rangle$ instead of $\langle \{x, y\} \rangle$.

A **one-generated** subgroup is a subgroup generated by one element, such as $\langle g \rangle$. A one-generated subgroup is also called a **cyclic** subgroup. A **two-generated** subgroup is a subgroup $\langle x, y \rangle$ generated by two elements, x and y . An **n -generated** subgroup is a subgroup of the form $\langle x_1, \dots, x_n \rangle$, which is generated by the n -element set $\{x_1, \dots, x_n\}$.

Let G be a group and let H be a subgroup of G . It is important to note the distinction between the following two statements:

1. “The cyclic subgroup H has two generators x and y .”
2. “The subgroup H is generated by two elements x and y .”

The first sentence means $H = \langle x \rangle = \langle y \rangle$. That is, you can take either x or y as the generator of H . The second sentence means something entirely different, namely, $H = \langle x, y \rangle$. This says that the smallest subgroup of G that contains both x and y is H . It may or may not be the case that H is cyclic. The notation $H = \langle x, y \rangle$ simply means that H can be generated by two elements. It’s possible that we could find an element that generates H all by itself. That is, we may have $H = \langle g \rangle = \langle x, y \rangle$.

Examples

1. Consider the subgroup $H = \{e, (1, 2, 3), (1, 3, 2)\}$ of A_4 , which can be generated by either one (or both) of its non-identity elements: $H = \langle (1, 2, 3) \rangle = \langle (1, 3, 2) \rangle$.
2. Continuing with the last example, we could write $H = \langle (1, 2, 3), (1, 3, 2) \rangle$. Here we have thrown in a redundant generator, which is harmless but not helpful because it doesn’t call attention to an important feature of H —namely, that it is one-generated, i.e., cyclic.
3. As mentioned above, the subgroup of \mathbb{Z}_{12} generated by the set $\{4, 6\}$ is $\{0, 2, 4, 6, 8, 10\}$. To see this, note that, if 4 and 6 belong to a subgroup of \mathbb{Z}_{12} , then so must $4 + 4 = 8$ and $4 + 6 = 10$ and $6 + 6 = 0$ and $4 + 4 + 6 = 2$.
4. Suppose $G = \langle a \rangle$ is a cyclic group, suppose $x = a^6$ and $y = a^8$. Then

$$H = \langle x, y \rangle = \langle a^6, a^8 \rangle = \langle a^2 \rangle.$$

5. Unlike all of the previous examples, the group $\mathbb{Z}_2 \times \mathbb{Z}_2$ is not cyclic. You need at least two elements to generate this group. For example, you could use $(0, 1)$ and $(1, 1)$ (though there are other options):

$$\mathbb{Z}_2 \times \mathbb{Z}_2 = \langle (0, 1), (1, 1) \rangle.$$

6. The **Klein 4 group**, typically denoted by V_4 , is a two-generated subgroup of A_4 . It is generated by any pair of non-identity elements, say, $(1, 2)(3, 4)$ and $(1, 3)(2, 4)$:

$$V_4 = \langle (1, 2)(3, 4), (1, 3)(2, 4) \rangle = \{e, (1, 2)(3, 4), (1, 3)(2, 4), (1, 4)(2, 3)\}$$

Again, we could have used a different pair, say, $(1, 3)(2, 4)$ and $(1, 4)(2, 3)$, to generate V_4 . The point is that we need more than one element, so V_4 is not cyclic.

It turns out that the Klein 4 group is essentially the same as the group $\mathbb{Z}_2 \times \mathbb{Z}_2$. As we will see later, these two groups are “isomorphic,” which is an idea that we have surely thought about when comparing groups, but have left undefined for the moment.
